Khwārizmī: Muḥammad ibn Mūsā al-Khwārizmī

Sonja Brentjes

Born circa 780

Died circa 850

Khwārizmī was a well-known astronomer and mathematician who spent most, if not all, of his scholarly life in Baghdad, in close connection with the ’Abbāsid court, particularly during the caliphate of Ma’mūn (reigned: 813-833). There is some confusion about his origins. The 10th-century bibliographer Ibn al-Nadīm claimed that Muḥammad ibn Mūsā was from Khwārizm in Central Asia, whereas the historian Ṭabarī reported that Khwārizmī was also known as al-Qūṭrabbulī, a name associating the scholar with a town not far from Baghdad rather than with the Central Asian region of Khwārizm (Toomer, p. 358). Ṭabarī added that he was also called al-Majūsī, a designation that indicates that Khwārizmī was a Zoroastrian rather than a Muslim. Ibn al-Nadīm also stated that he was attached to the Bayt al-hikma, the caliphal library. What this means exactly is unclear since there is considerable modern controversy about this institution and whether it should be regarded simply as a library or as a translation bureau and scientific research institution.

Ibn al-Nadīm lists four astronomical works: the Zīj al-Sindhind (an astronomical handbook according to the Sindhind), a treatise on the sundial, and two works on the astrolabe. Of these, the first is no longer extant in Arabic but is available in Latin translation; the second seems to be extant as are fragments of a work on the astrolabe. Rosenfeld and Ihsanoğlu list 20 astronomical works in all. Among Khwārizmī’s nonastronomical works at least two are mathematical: a book on Indian arithmetic and one devoted to algebra. (A book on “addition and subtraction” is also attributed to him.) He also has a Book on Geography, which is extant, and a Book on History, which is not but was quoted by later authors. The Algebra and the Zīj were dedicated to Caliph Ma’mūn. The treatise on Indian arithmetic in its extant Latin translation mentions the Algebra and hence was produced later. Khwārizmī also wrote a description of the Jewish calendar, which was written not before 823/824 because one of its examples is carried out for that year. The other texts offer no clue for dating them.

Khwārizmī’s Zīj al-Sindhind confirmed the place of pre-Islamic Indian astronomical models, functions, and parameters in the scholarly community of Baghdad, which had been multicultural since the second half of the 8th century. Before him, several “Zījāt al-Sindhind” are said to have been compiled based on Arabic translations of Indian astronomical handbooks (Pingree 1970, p. 105). Indeed, the astronomer Ibn al-Ādāmī described Khwārizmī’s Zīj as an abridgment, prepared for Ma’mūn, of Fazārī’s (second half of the 8th century) handbook al-Sindhind (Pingree 1970, p. 106). Khwārizmī’s tables were known to astronomers not only in Baghdad, but also in Central Asia in the east and in Andalusia on the Iberian Peninsula in the west. A number of authors who compiled their own handbooks relied on it. Two examples are the already-mentioned Ibn al-Ādāmī in Baghdad, in his nonextant astronomical handbook Naẓm al-liqād, and Ibn Mu’ādh in Andalusia, whose handbook is extant in its Latin translation Tabulae Jahan. Others commented on Khwārizmī’s tables, often criticizing the methods used, such as Ahmad ibn Kathīr al-Farqhānī (9th century) in Baghdad, Ibn al-Muthannā (10th century?) in Andalusia, ‘Abdallāh ibn Masrūr al-Ḥasīb al-Naṣrānī in Baghdad (9/10th centuries), and Abū Rayhān al-Birūnī in Ghazna. Birūnī devoted three treatises to Khwārizmī’s Zīj. In one of them he defended Khwārizmī against attacks of Ahmad ibn al-Ḥusayn al-Ahwāzī (10th century) (Muḥammad ibn Mūsā 1983, p. 21). It is believed that as late as the 19th century, tables connected to Khwārizmī’s Zīj were copied in Egypt (Goldstein and Pingree 1978; Pingree 1983).
No copy of Khwārizmī’s Zīj has survived, but Hebrew and Latin versions of various later texts connected with Khwārizmī’s tables are extant. Ibn al-Muthannā in Andalusia set out to compose a commentary in order to rectify the obscurities of a critique of Khwārizmī’s tables written by Farghānī. Both commentaries are lost. But Hebrew and Latin versions of Ibn al-Muthannā’s commentary are extant (Goldstein 1967, pp. 5–6; Pedersen, p. 32). The Latin translation of Ibn al-Muthanna’s commentary was made by Hugo of Santalla (12th century) (Millās Vendrell, 1963). One Hebrew translation was produced by Abraham ibn Ezra (Goldstein 1967, p. 3). In the same century as Ibn al-Muthannā and also in Andalusia, Maslama ibn Ahmad al-Majritī edited Khwārizmī’s tables. Majrītī’s student Ibn al-Saffār is believed to have continued the editorial work of his teacher (Toomer, p. 358). This edition was translated in the 12th century into Latin presumably by Adelard of Bath. Other Latin manuscripts contain texts that seem to combine extracts from Ibn al-Muthannā’s commentary, Majrītī’s edition, and one or more Arabic compilations of material, translated and revised into Latin, from the tables of Khwarizmi. Yāhū Ḫūn Abī Mānsūr, Muhammad ibn Jābir al-Battānī, Ibn al-Muthannā, and Majrītī (Pedersen, pp. 31–46). The Toledan Tables, compiled around 1060 in Muslim Spain, contain several tables from Khwarizmi’s Zīj, some of which are not found in Majrītī’s revision. They are lost in Arabic, but extant in several Latin versions (Dalen, p. 200).

The extant texts and tables follow in their presentation of the material; in their methods, rules, and models; and in several of their parameter values astronomical knowledge and practice as taught in several treatises written by Hindu scholars between the 5th and 7th centuries. They also use elements from Sasanian astronomical tables, incorporate borrowings from Greek astronomical writings (in particular Ptolemy’s Almagest and Handy Tables), and include values determined by observations carried out during Ma’mūn’s reign. A survey of the character of the tables in the Latin translation of Majrītī’s revision of Khwārizmī’s Zīj has recently been given by Dalen (pp. 200–211). Khwārizmī’s original Zīj has been described as a similar mixture of elements by Ibn al-ʿĀdāmī, who, according to Ibn al-Qīṭī (1173–1248), had reported that Khwārizmī had relied in his work on the mean motions of the Indian tradition, but differed from it in the equations and the declination. Ibn al-ʿĀdāmī also asserted that Khwārizmī followed Sasanian sources with regard to the equations and Ptolemy when he dealt with the declination of the Sun (Pingree 1970, p. 106). According to McCarthy and Byrne, Khwārizmī’s original handbook juxtaposed tables, which addressed the same kind of tasks, but came from different cultural origins. Examples illustrating the diverse components in the extant texts and tables and their modifications are the replacement of the Yazdagird calendar by the Hijra era, the addition of calendars alien to the traditions in India such as the ancient Egyptian, Seleucid, Roman, and Christian eras, the use of theorems (such as the Menelaus theorem) that were unknown to Hindu astronomers, the use of the value for the obliquity of the ecliptic as found in Ptolemy’s Handy Tables, the use of the Ptolemaic value of $66 \frac{2}{3}$ miles for a terrestrial degree, and the replacement of the latitude of Baghdad by the latitude of Cordova (Neugebauer, p. 19; Kennedy and Janjanian, pp. 73, 77; Goldstein 1967, pp. 7–8; Dalen, 1996, pp. 196, 240).

Khwārizmī’s treatise on the Jewish calendar gives rules for determining the mean longitude of the Sun and the Moon based on this calendar and for determining on what day of the Muslim week the first day of the New Year shall fall. It also discusses the 19-year intercalation cycle and the temporal distance between the beginning of the Jewish era, i. e., the creation of Adam and the beginning of the Seleucid era (Kennedy, 1964, pp. 55–59; Toomer, p. 360). The treatise on how to work with an astrolabe is only fragmentarily preserved, and opinions vary as to whether these fragments in their present-form represent the genuine version of what Khwārizmī actually wrote. The treatise on how to construct an astrolabe seems to be lost. Khwārizmī’s book on geography Kitāb Ṣūrat al-ard combines substantial parts of Ptolemy’s Geography with many non-Ptolemaic coordinates and place names. His two writings on arithmetic, one in the tradition of oral reckoning and the other according to the Indian tradition of written reckoning using the decimal place-value system, are lost in Arabic. The latter is extant in various Latin manuscripts. Khwārizmī’s book on algebra is the first known in Arabic. It treats quadratic equations, the measurement of areas and volumes, commercial problems by means of four proportional quantities, and several types of Muslim inheritance mathematics. This text too was translated into Latin by at least two translators. Its influence upon elementary algebra in Arabic, Persian, Ottoman Turkish, Latin, and European vernacular languages was substantial.

Finally, it is worth mentioning that Khwarizmi may have participated in a number of scientific expeditions, one to measure the size of the Earth, the other to explore the regions north of the Caspian Sea (Matvievskaia and Rozenfeld, 1983, Vol. 2: p.41). The first, though, has been recently questioned (King, 2000).

Muḥammad ibn Mūsā al-Khwārizmī?

Yes, Muḥammad ibn Mūsā al-Khwārizmī! There is no need to be an expert on the period or a philologist to see that al-Tabari's second citation should indeed be 'Muḥammad ibn Mūsā al-Khwārizmī' and al-Majūsi al-Qutrubi, and that there are two people (al-Khwārizmī and al-Majūsi al-Qutrubi) between whom the letter wa [Arabic 'و' for the article 'and'] has been omitted in an. Å detainé Al-Khwārizmī’ s Astronomical Tables Revisited: Analysis of the Equation of Time. Å In From Baghdad to Barcelona: Studies in the Islamic Exact Sciences in Honour of Prof. Juan Vernet, edited by Josep Casulleras and Julio Samsá. Al-Khwārizmī, in full Muḥammad ibn Mūsā al-Khwārizmī, (born c. 780 â€“died c. 850), Muslim mathematician and astronomer whose major works introduced Hindu-Arabic numerals and the concepts of algebra into European mathematics. Latinized versions of his name and of his most famous book title live on in the terms algorithm and algebra. Top Questions. What is al-Khwārizmī famous for? Al-Khwārizmī is famous for his mathematical works, which introduced Hindu-Arabic numerals and algebra to European mathematicians. In fact, the words algorithm and algebra come from his name and the title of one of his works. Previous (Muhammad ibn Abd-al-Wahhab). Next (Muhammad ibn Zakariya al-Razi). Muḥammad ibn Māsā al-Khwārizmī (Arabic: مُجَيَّد بن مُسَدُّر) (780–850) was a Persian mathematician, astronomer, astrologer and geographer. He was born around 780 in Khwārizm (now Khiva, Uzbekistan) and died around 850. He worked most of his life as a scholar in the House of Wisdom in Baghdad.
